

# Towards full-waveform inversion of the near surface in exploration seismic

Philip Knaute,  
Keith Priestley, James Rickett,  
Colin Thomson

# The growing importance of near surface signals

- Industry often considers ground roll as noise
- Near surface can distort deeper signals
- New technology makes high-fidelity land-seismic surveys possible

# The growing importance of near surface signals

- Industry often considers ground roll as noise
- Near surface can distort deeper signals
- New technology makes high fidelity land-seismic surveys possible
- Characterisation and exploitation of unconventional reservoirs like shale gas/oil need very good (surface) velocity models to compensate for near-surface effects

North American crude production by asset type, 2010-2020

Source: IEA, IHS CERA, Business Monitor International, PFC Energy, SLB analysis

# Survey location

## North-east British Columbia

- shale gas rich area
- shale gas exploitation booming for the last decade
- reservoirs 2000-2500m depth

Cordova  
Embayment

# Typical surface characteristics in the Cordova Embayment area

*Source: Photos by Garth Lenz*

# Survey characteristics

- Number of shots in total : 868

- Three kinds of shots

S-Vib sources / P-Vib source /  
Impulse source

- Vibration data, correlated

Klauder wavelet as effective  
source wavelet

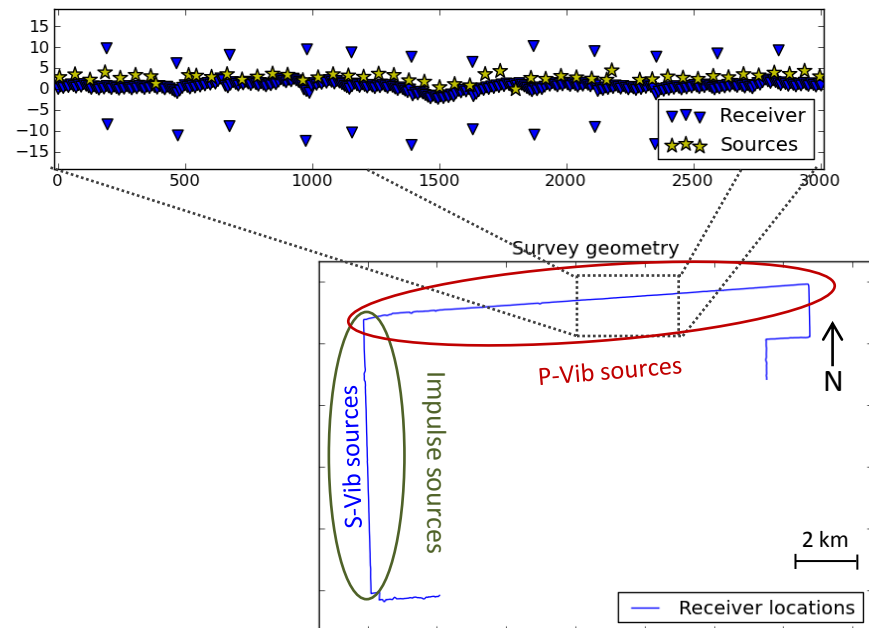

- Shot spacing :  $\sim 60\text{m}$

- Receiver spacing :  $\sim 10\text{m}$

- 3-comp acceleration data

- 2ms time sampling

- 6s record length

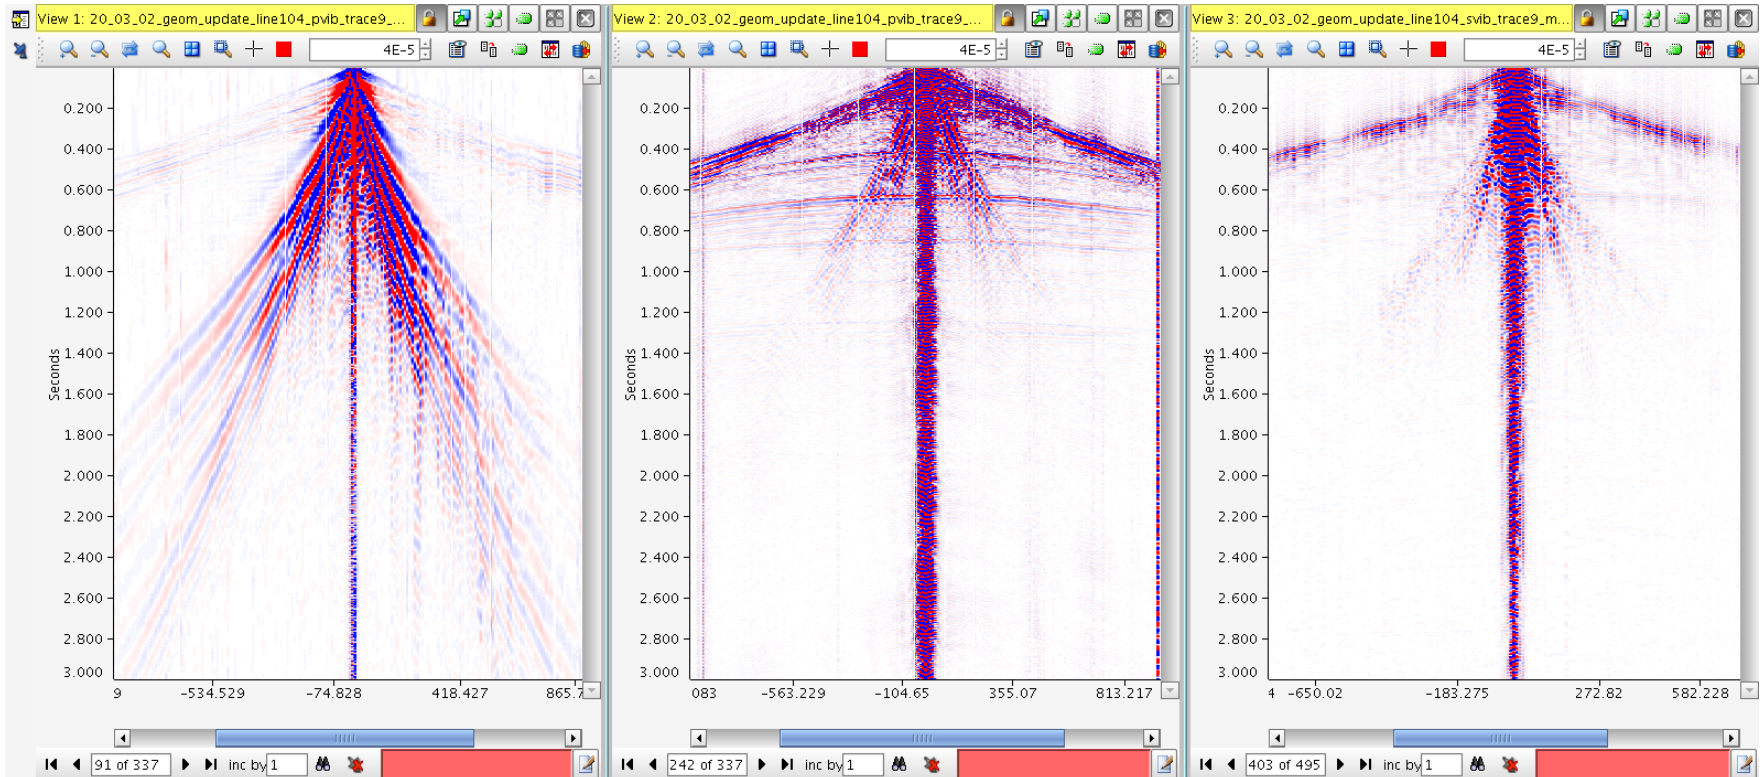

# Influence of the source-time function

The *source-time-function* (time-dependent amplitude of the force applied at the source) can have a large impact on the recorded seismograms

Impulse source

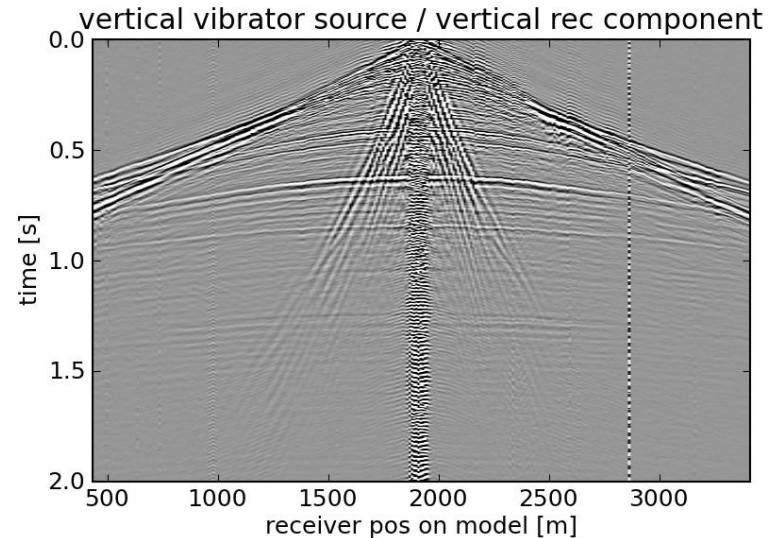

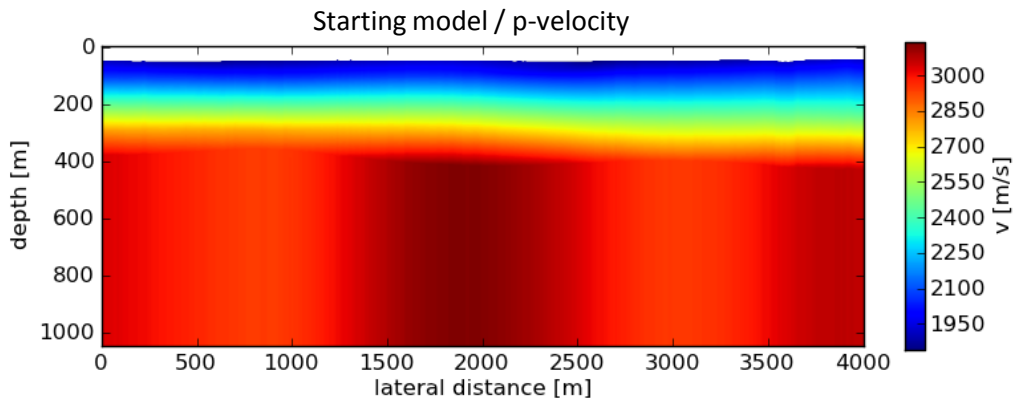

Vertical vib source

Horizontal(SH) vib source

# Investigated part of survey

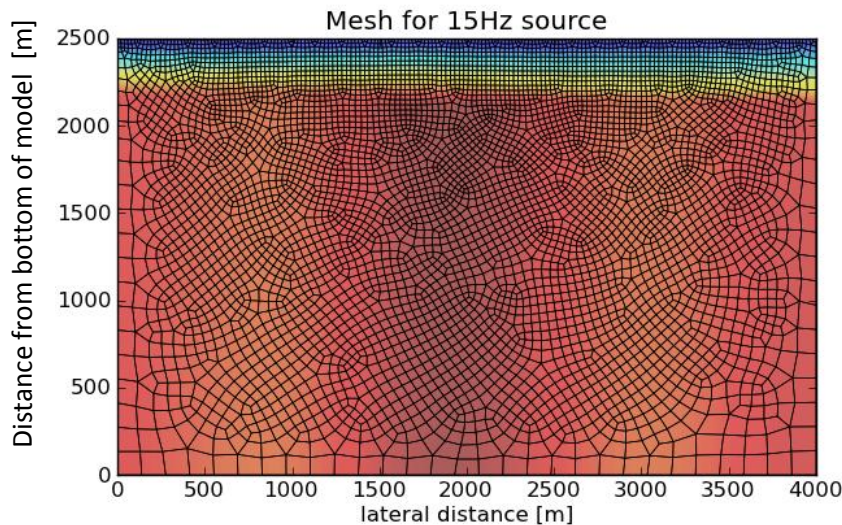

- Lateral extent: 4km
- Number of shots: 66
- Number of receivers per shot: ~300
- offset per shot : -1500m to 1500m
- P-Vib source ( ~8-120 Hz )

# Calculating synthetics with SEM method

## Mesh for the SEM calculations

Guideline for accuracy :

$$\frac{v_{min}}{f_{max}} \approx \Delta h$$

Stability criterion for time marching:

$$\Delta t \approx 0.3 \cdot \left( \frac{\Delta \hat{h}_{point}}{v} \right)_{min}$$

Typical parameter values for on forward simulation at  $f_{max} = 15\text{Hz}$ :

$$\Delta h_{max} = 104m \quad \Delta t = 3.0 \cdot 10^{-4}s$$

$$\Delta h_{min} = 23m \quad 5519 \text{ elements}$$

Simulation time on 8 processors : ~ 2 min

# Compare recorded data to synthetics

Numerically generated data : synthetics

Recorded data

- 2D wave propagation
- displacement
- perfectly straight line

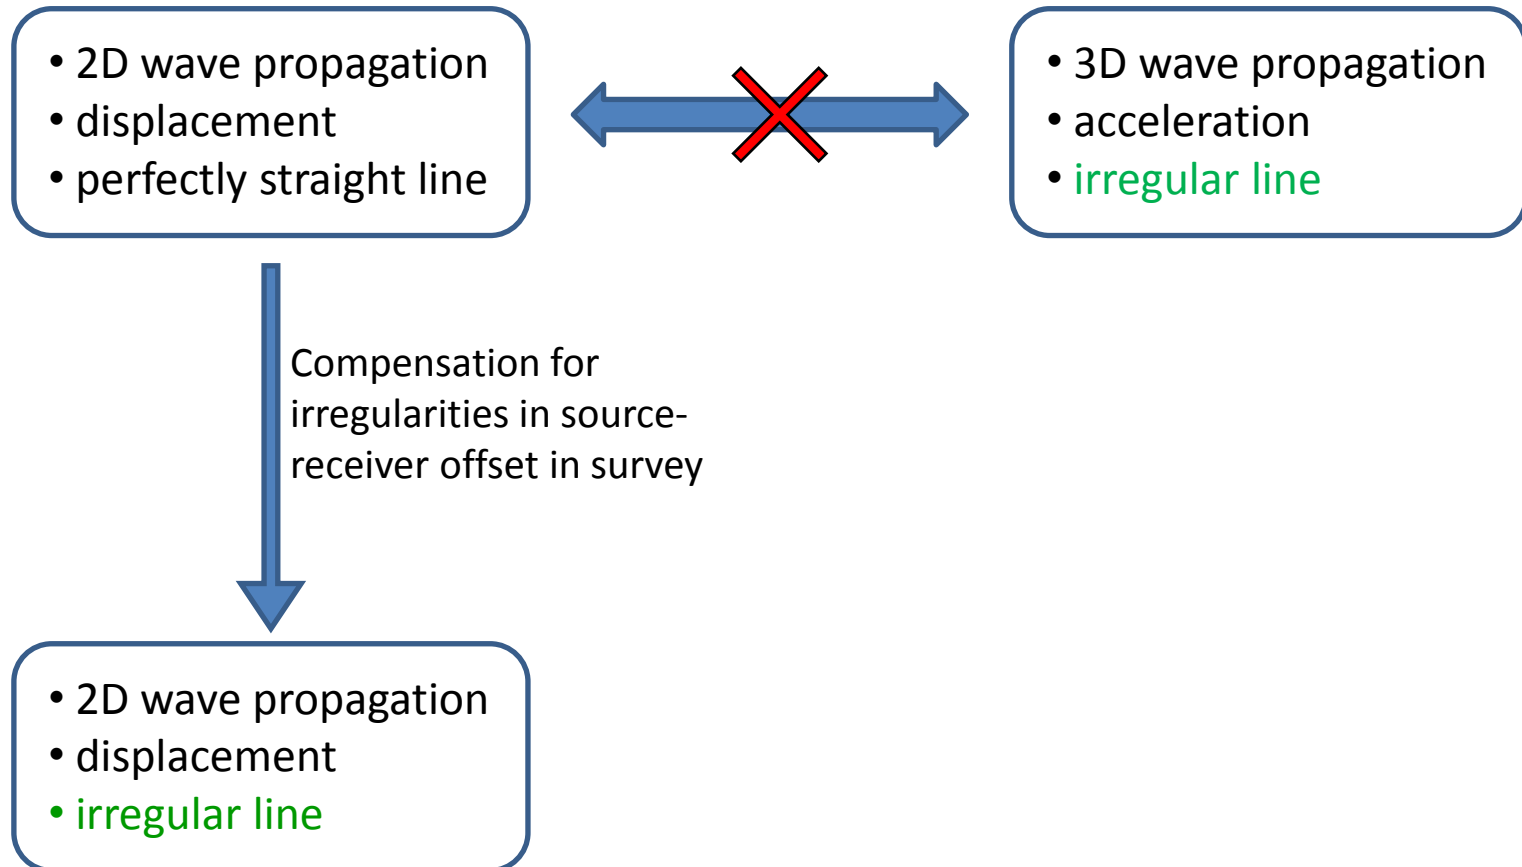

- 3D wave propagation
- acceleration
- irregular line

# Compare recorded data to synthetics

Numerically generated data : synthetics

Recorded data

# Preparations for correct modeling

*Receiver and source locations:*

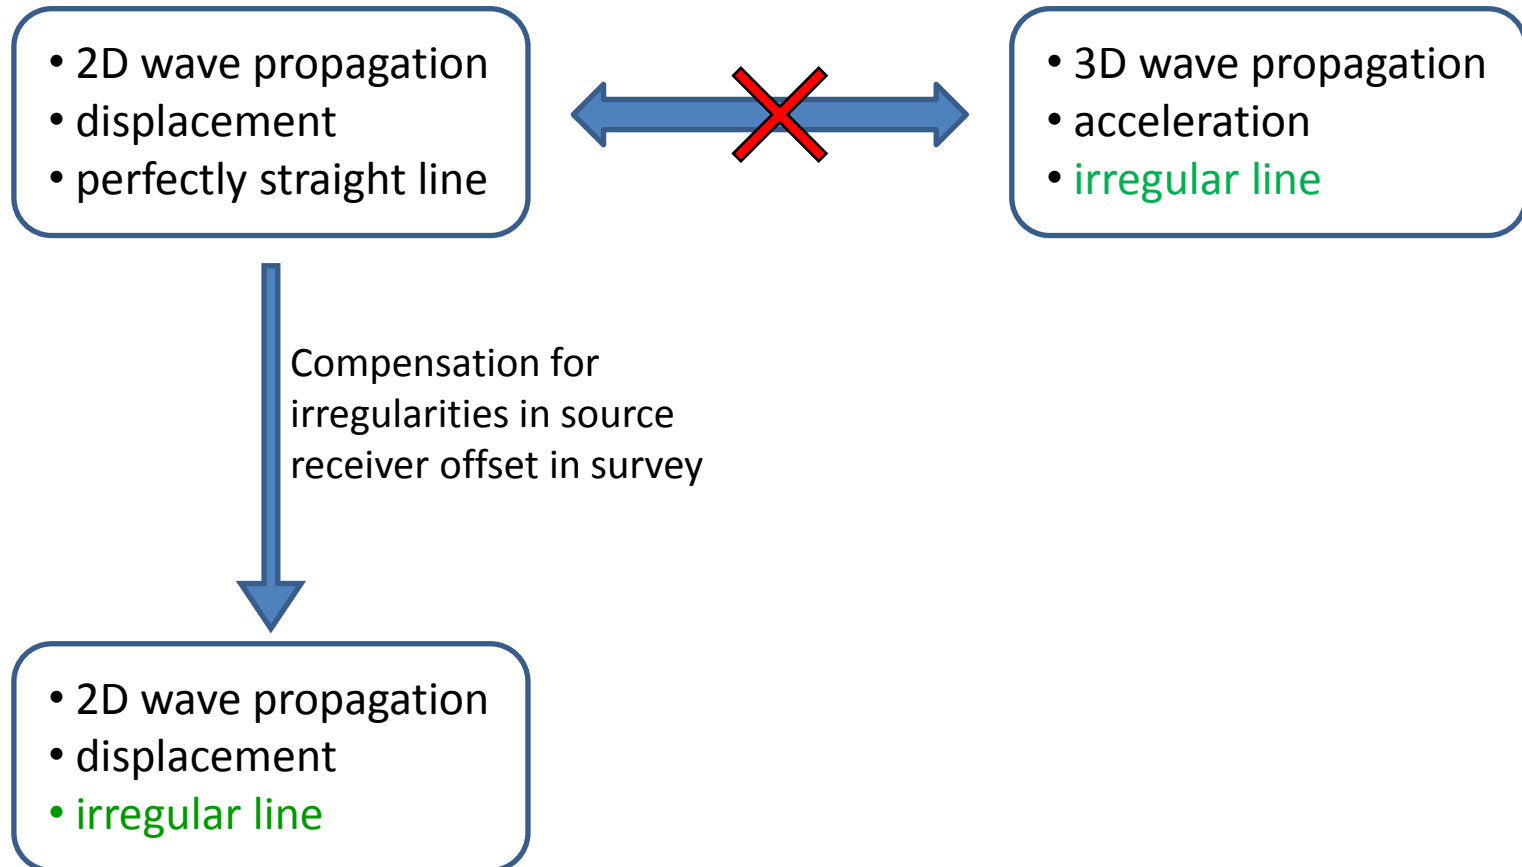

- > Remove receiver locations which are not on the main receiver line
- > Calculate corrected source and receiver distances on 2D Line

Numerically generated data : synthetics

Recorded data

- 2D wave propagation
- displacement
- perfectly straight line

- 3D wave propagation
- acceleration
- irregular line

3D to 2D transformation

Compensation for  
irregularities in source  
receiver offset in survey

- 2D wave propagation
- displacement
- irregular line

- 2D wave propagation
- acceleration
- irregular line

# 2D Simulation of 3D Data

Wave propagation excited by a point source is different in 2D and 3D

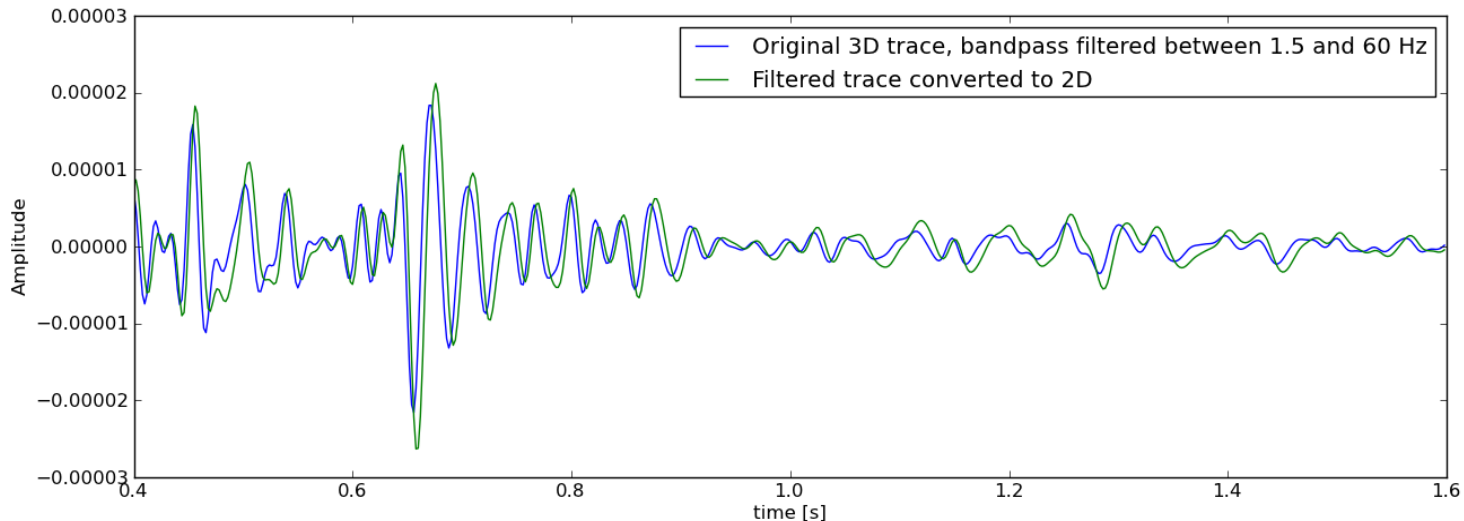

To compare 2D synthetics with 3D data it is necessary to transform the recorded 3D data to 2D

This can be done by convolving the recorded traces with the function:

$$H(t) \cdot t^{-\frac{1}{2}}$$

where  $H(t)$  denotes the step function

*(Chapman, GJRS, 1978)*

- displacement
- irregular line

# Compare recorded data to synthetics

Numerically generated data : synthetics

Recorded data

# Synthetic vs. data gather

Certain parts of the gather can be matched using only small adjustments to the starting model

Much more information is contained in the data and will be included in the process as our synthetics match our data better and better

# Band-passed data and synthetics

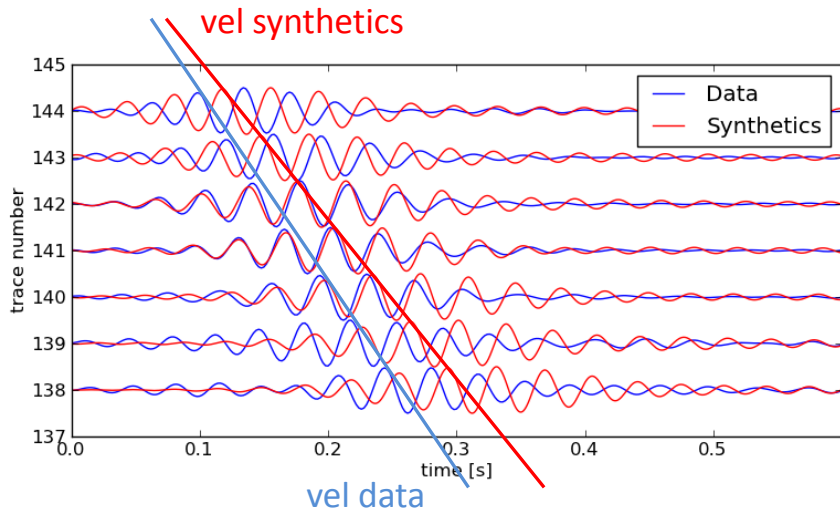

Rayleigh wave in band-passed (25-30Hz) data/synth

Velocity of near surface manually adjusted

Rayleigh wave in band-passed (25-30Hz) data/synth

# Future work

- Iterative inversion of the data
  - Perform the inversion
  - Iterate through arrivals -> Full waveform
  - Try different misfit functions  
(time-frequency, polarisation)
  - Chose appropriate optimisation algorithm
- Validating results
  - Comparing with results of other methods
  - Use finite-difference code to compare synthetics

Thank you
